Learning Objectives for this Lesson

By the end of this lesson, you should be able to...

- Relate continuous development to classic software process models (waterfall and agile)
- Identify the stages of a continuous development pipeline and describe how they relate to improving code velocity and quality

What is a software process?

- A structured set of activities required to develop a software product
 - Specification
 - Design and implementation
 - Validation
 - Evolution (operation and maintenance)
- Goal: Minimize Risk
 - Falling behind schedule
 - Changes to requirements
 - Bugs/unintended effects of changes

Software Verification and Validation

Quality Assurance

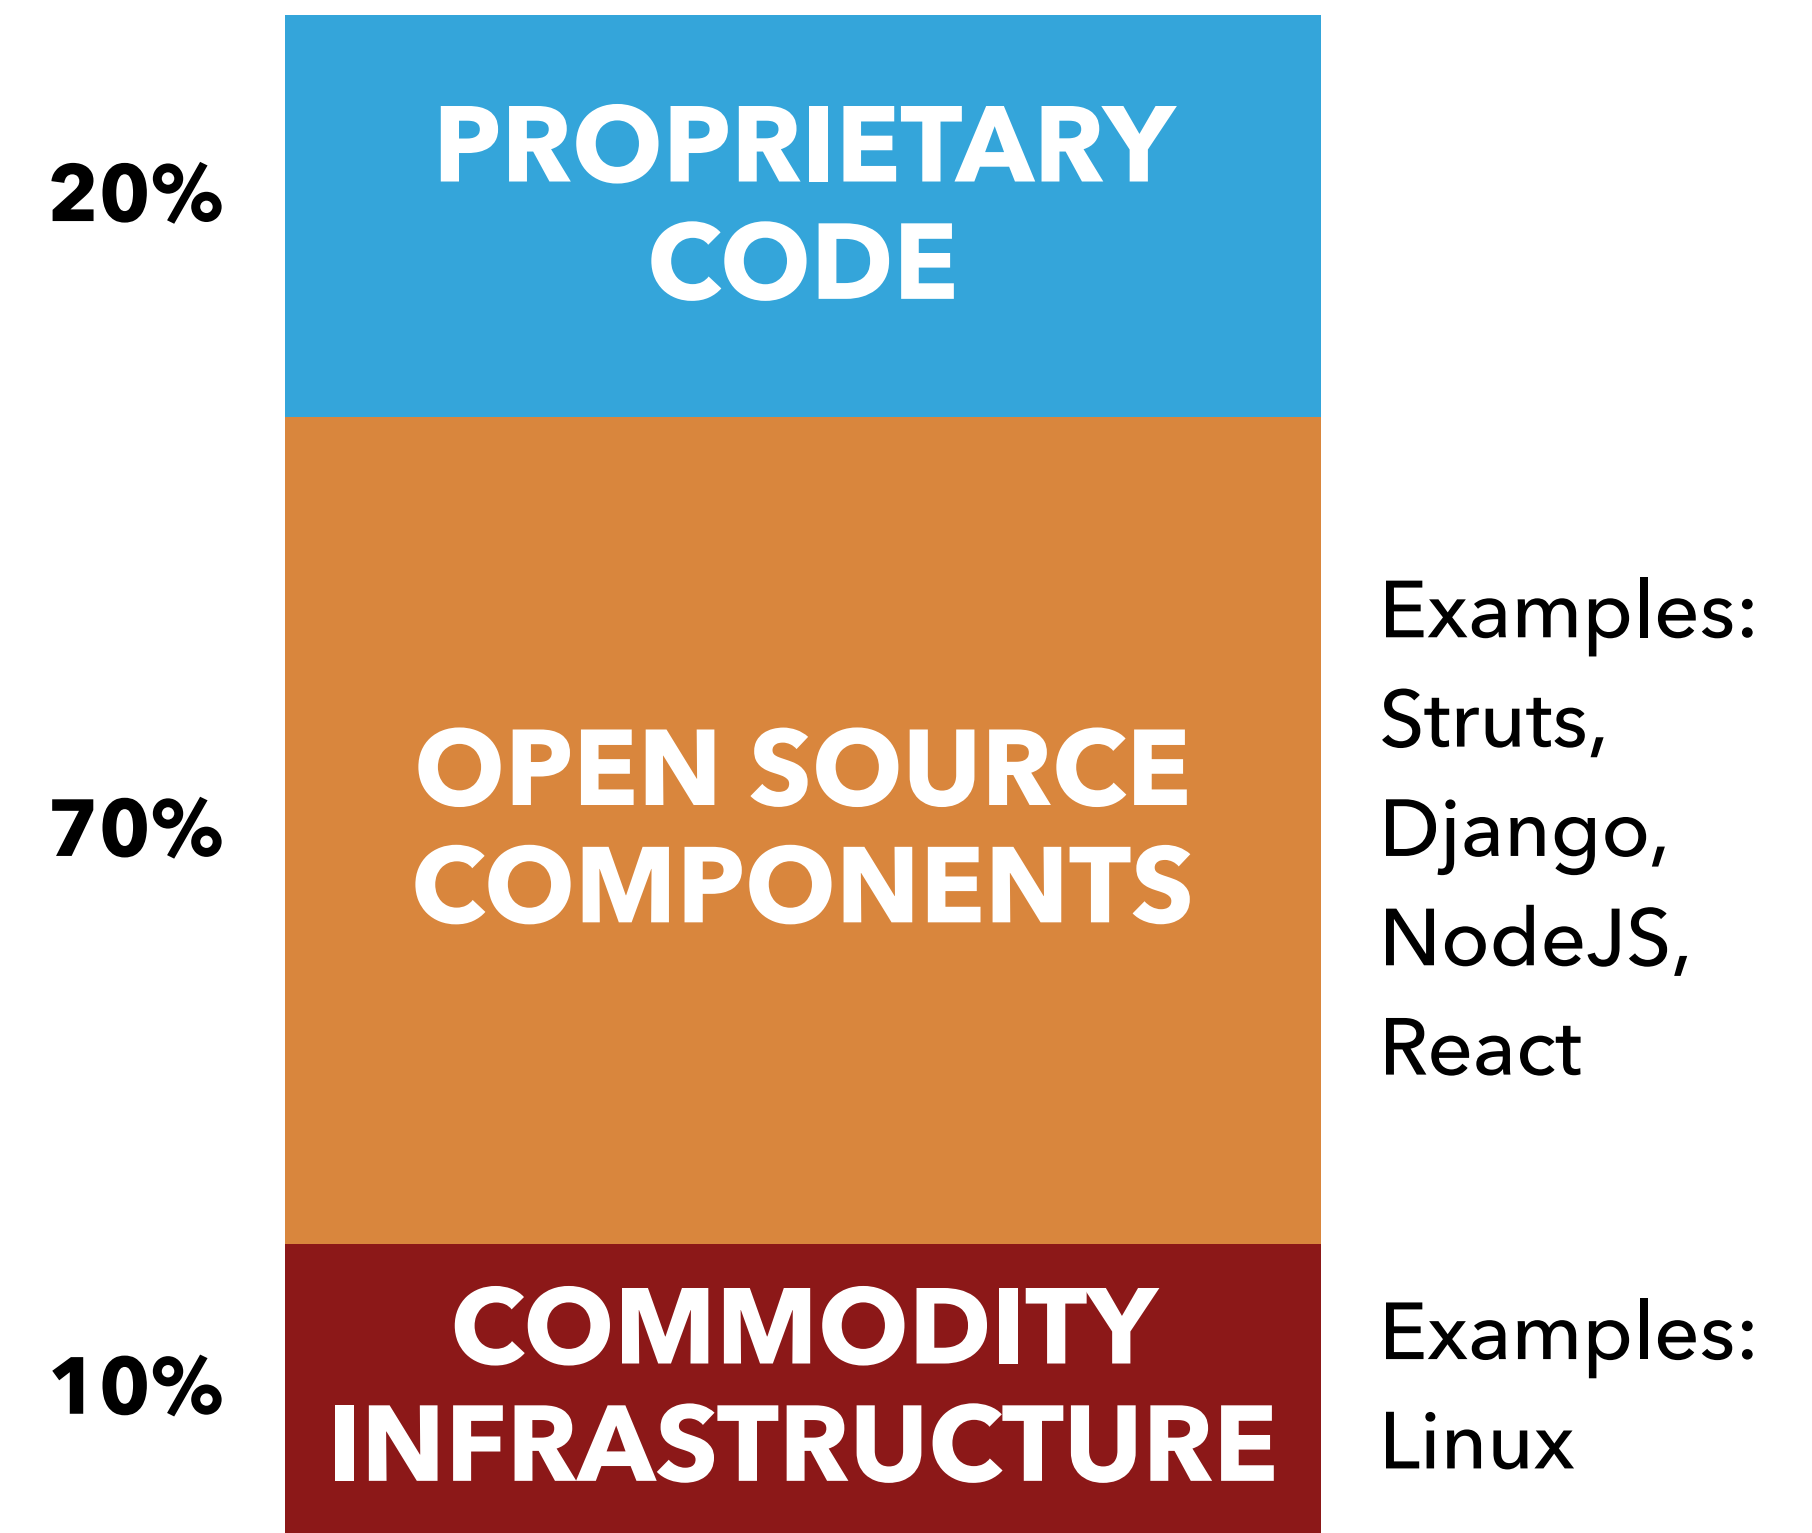

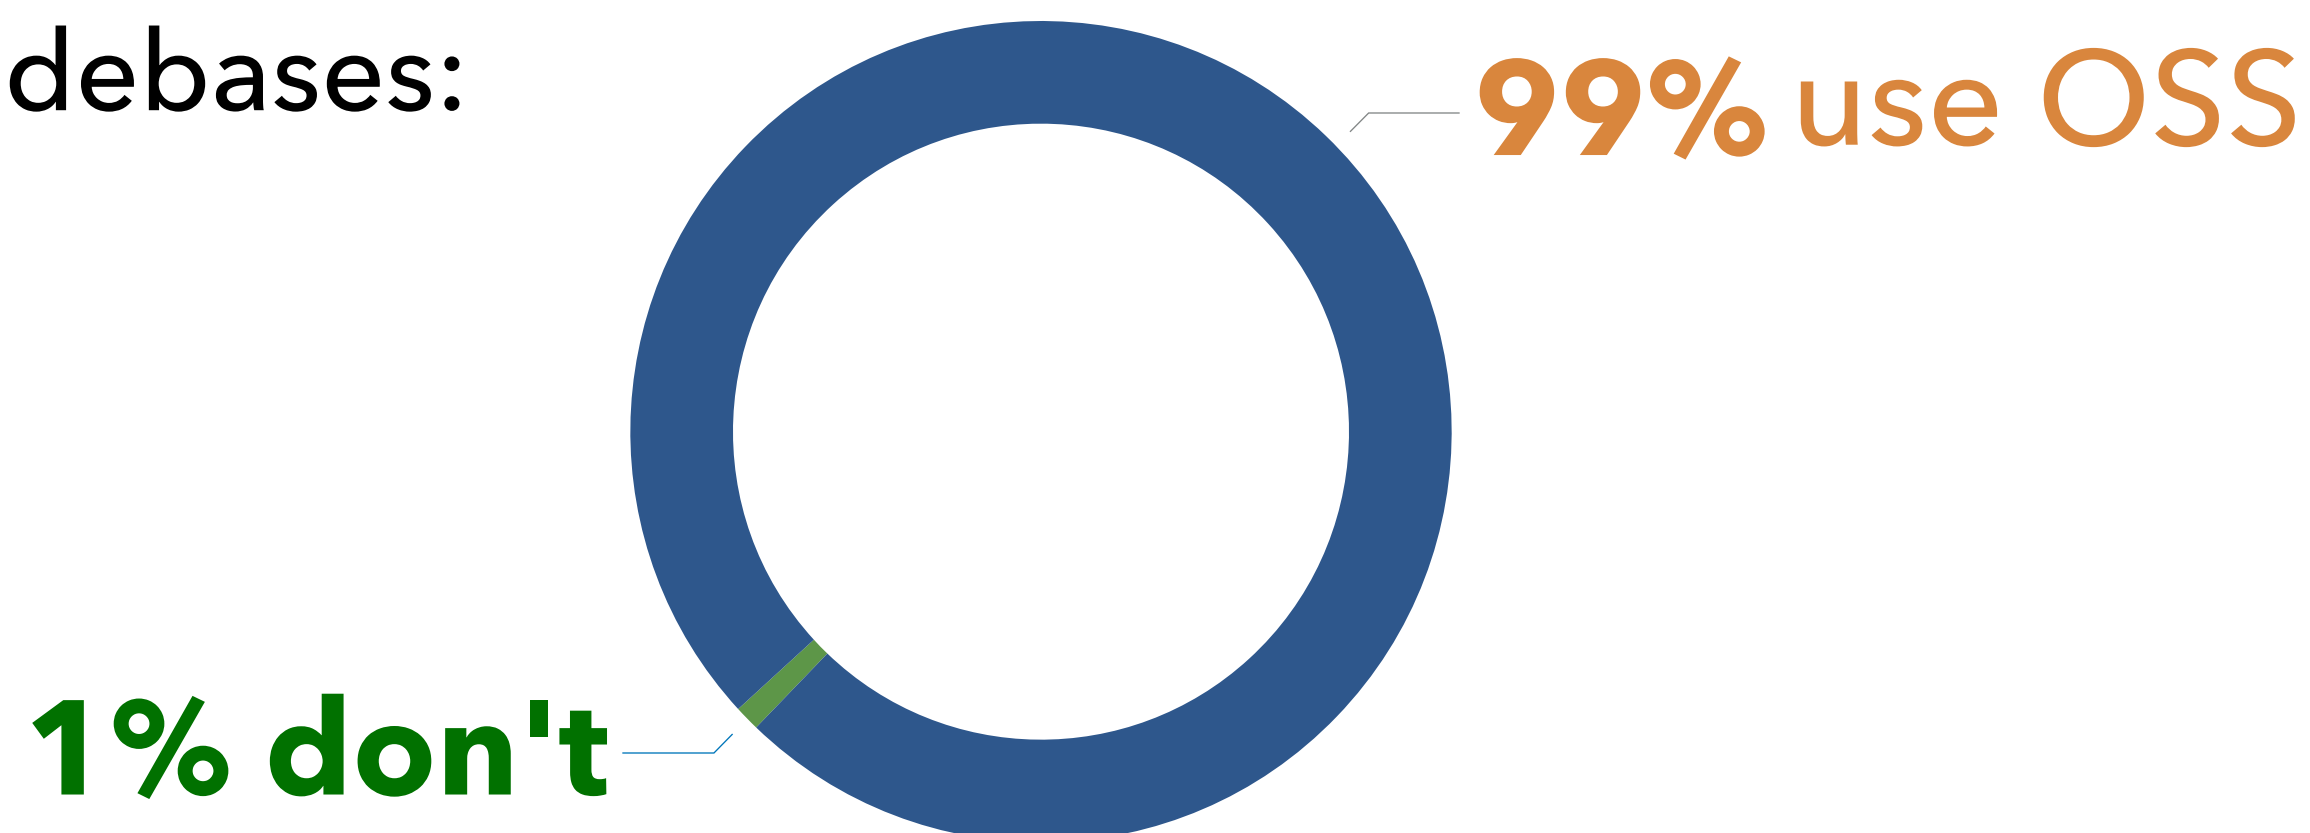

- Verification and validation (V & V) is intended to show that a system conforms to its specification and meets the requirements of the customer(s).
- Involves checking and review processes, and acceptance or beta testing.
- Custom software: Acceptance testing involves executing the system with test cases that are derived from the real data to be processed by the system in the customer's environment.
- Generic software: Beta testing executes the system in many customers' environments under real use.

Software Evolution

Software is inherently flexible: we want high development velocity!

- As requirements change due to changing business circumstances, the software that supports the business must also evolve and change.
- Most software today is built on large (and old) codebases

Synopsys (BlackDuck) 2019
audit of 1,200 proprietary
codebases:

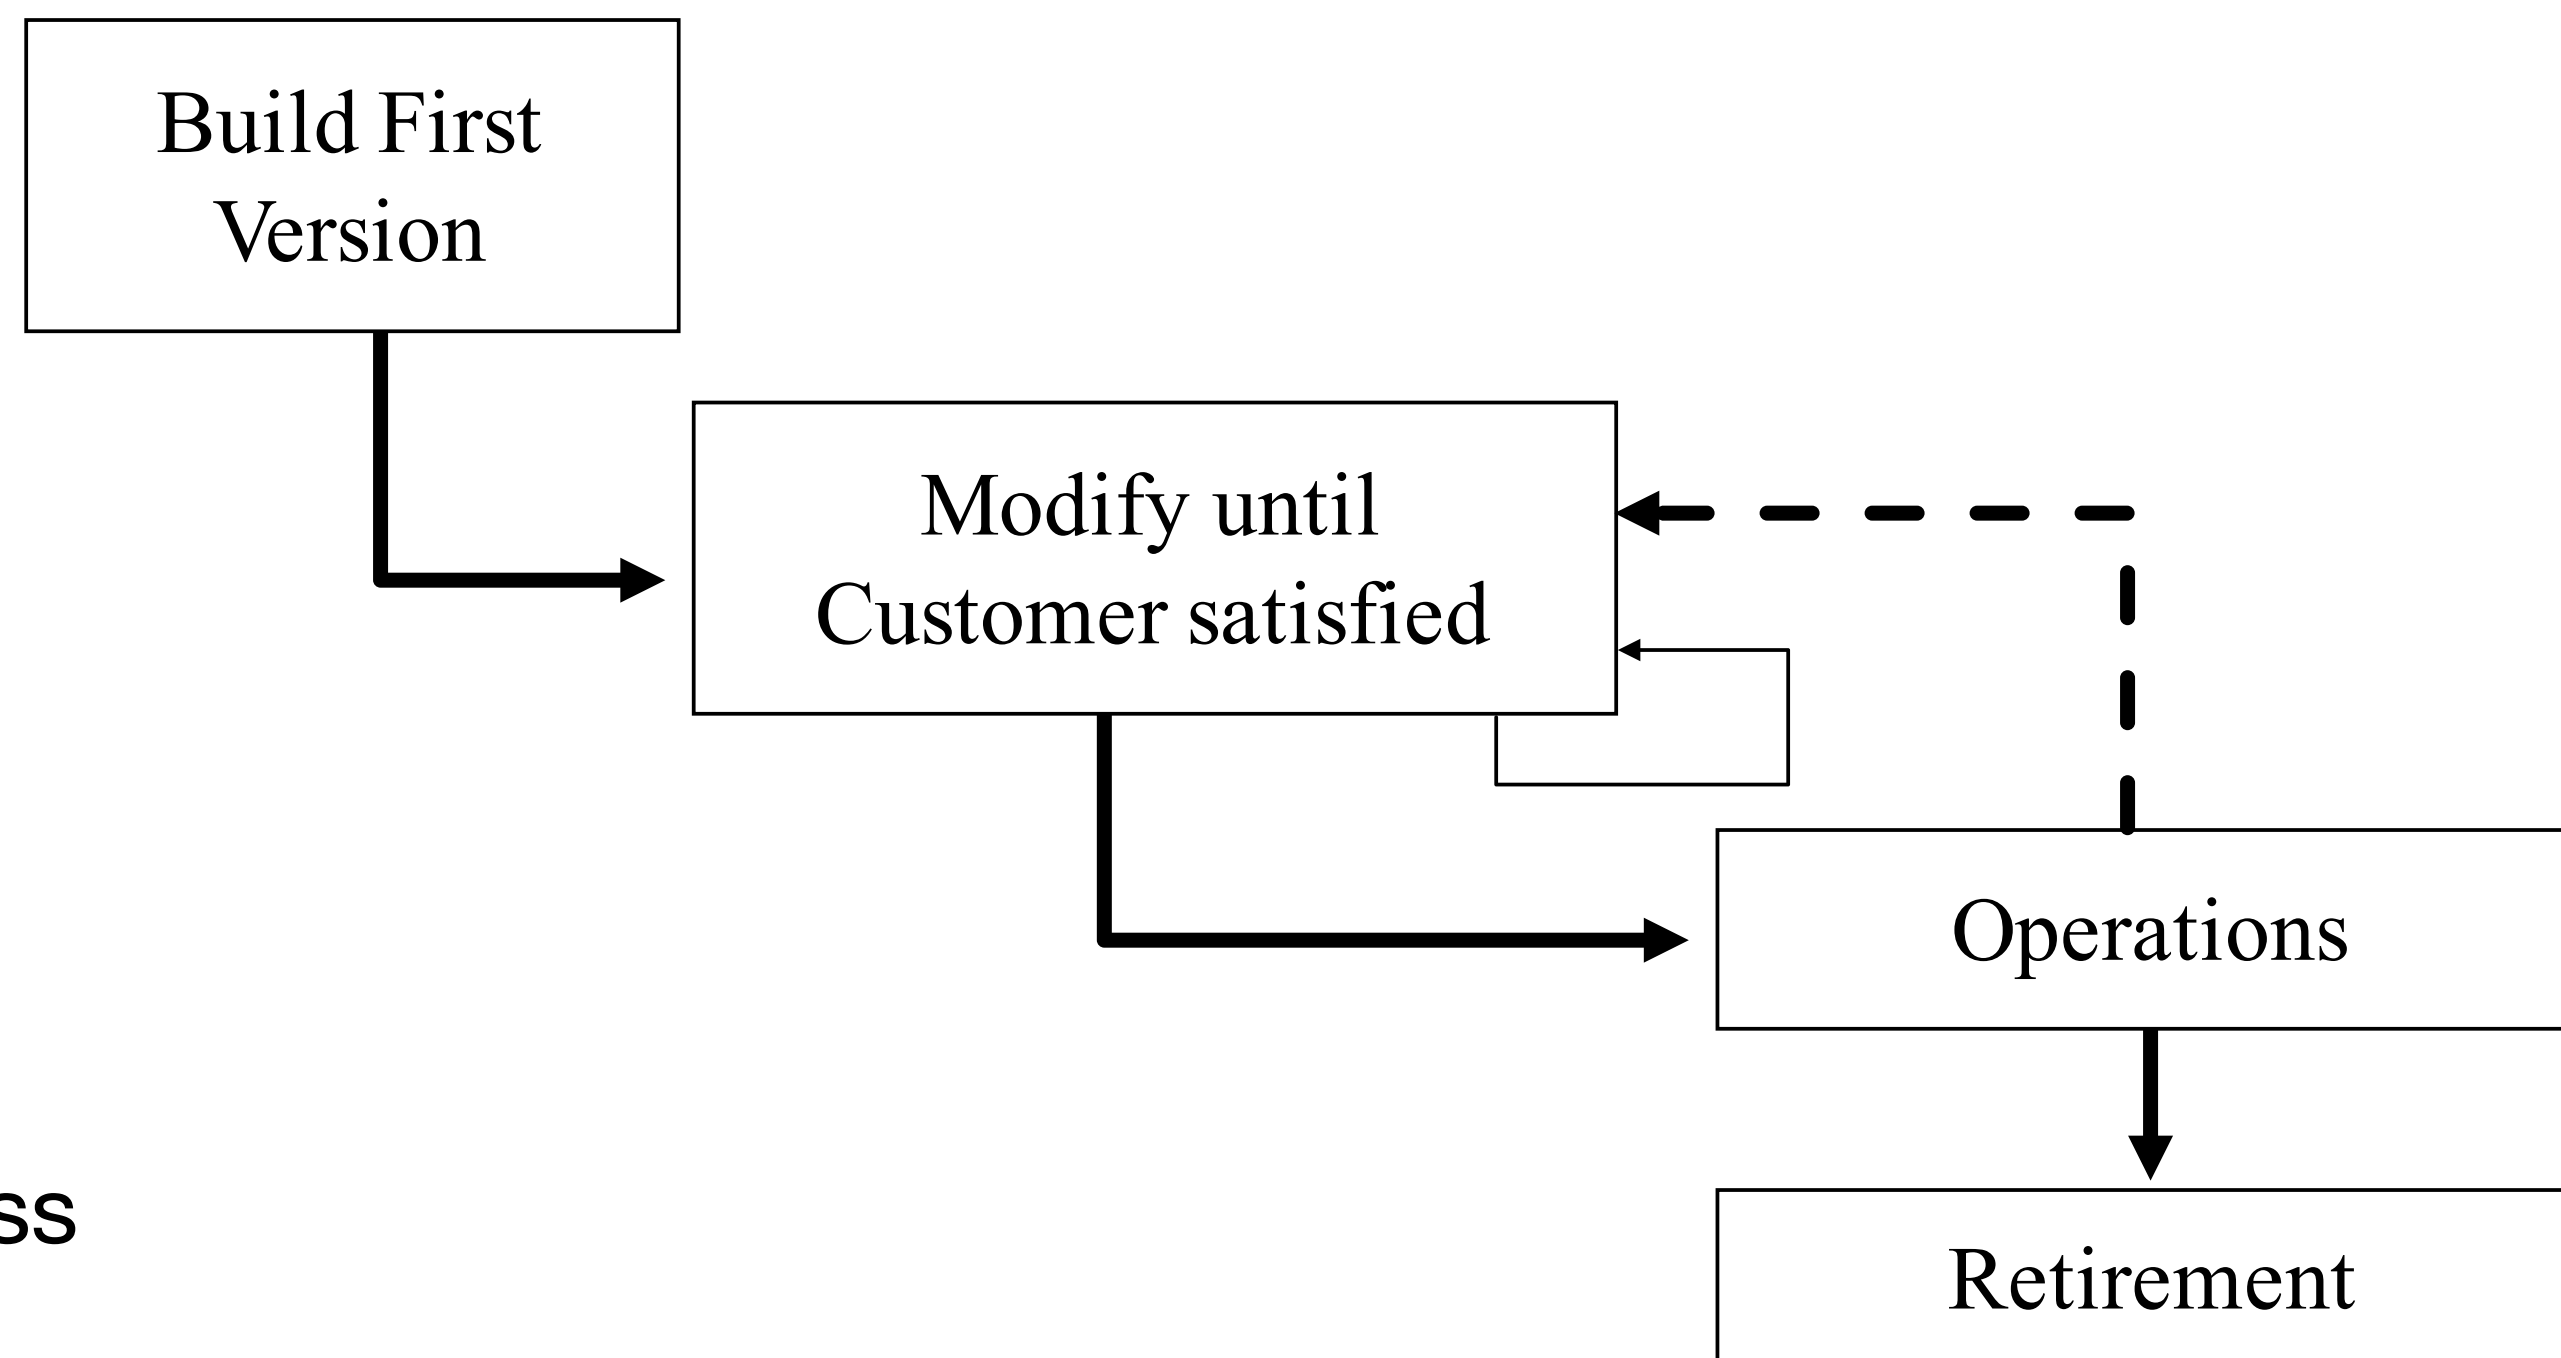

Process Models

- If we say that building software requires:
 - Specification
 - Design/Implementation
 - Validation
 - Evolution
- How do we structure our organization/development teams/tasks to do this most efficiently?

Software Processes

Code-and-fix

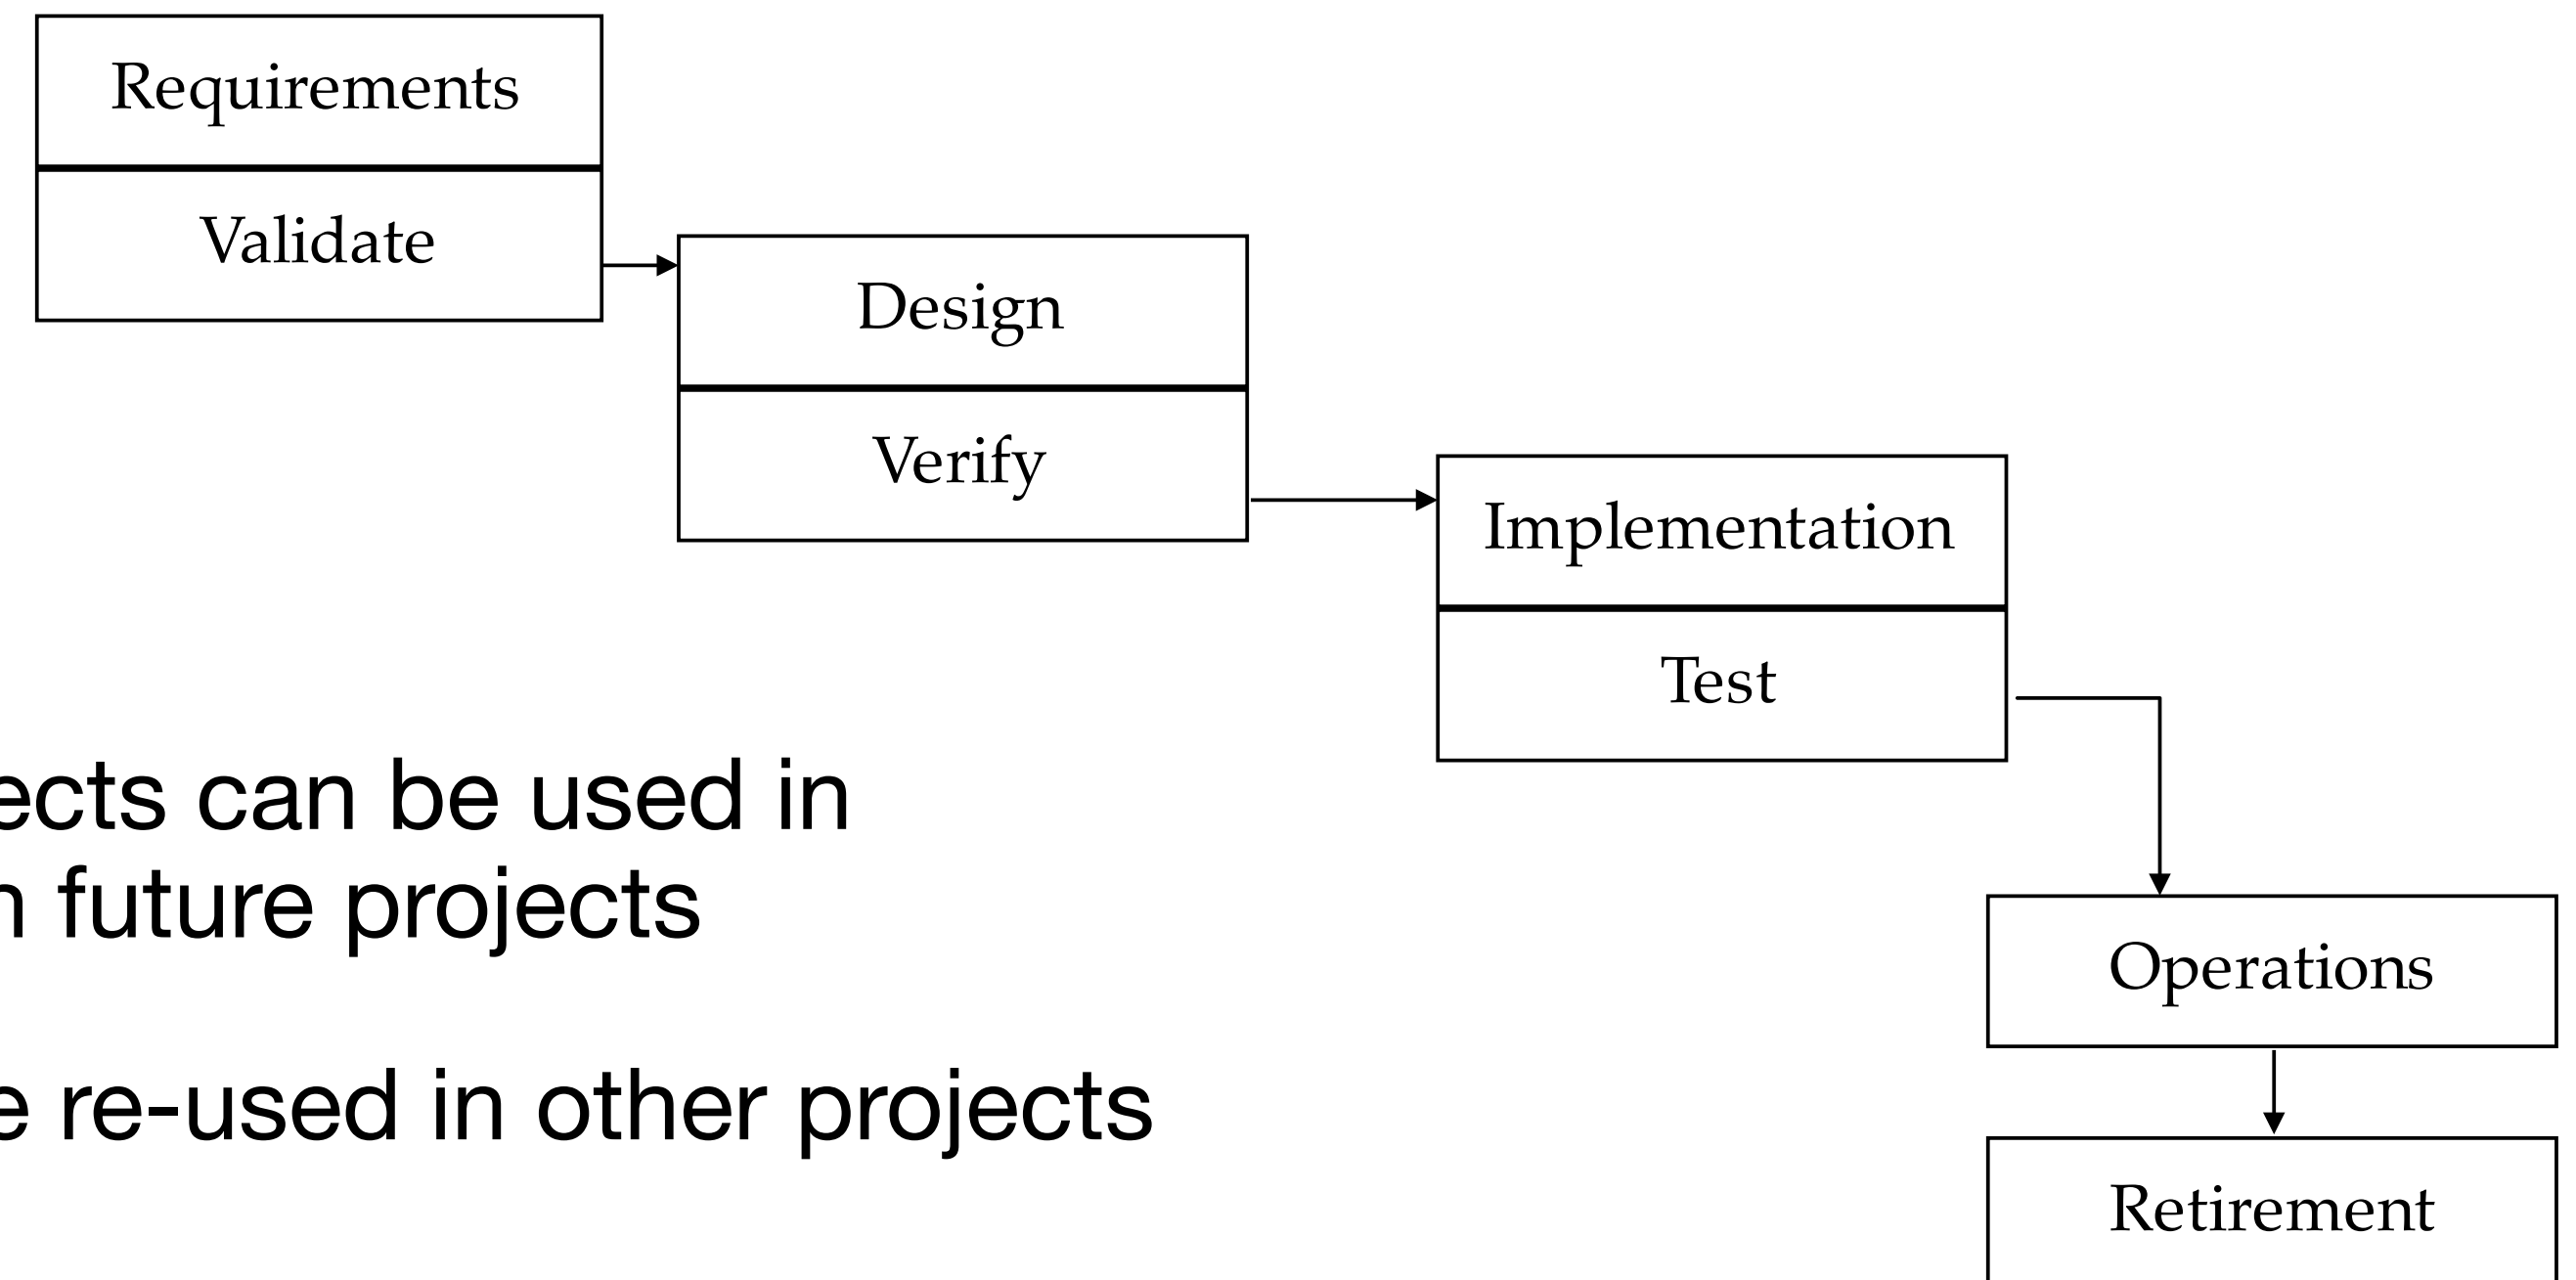

- Really Bad
- Really Common
- Advantages
 - No Overhead
 - No Expertise
- Disadvantages
 - No means of assessing progress
 - Difficult to coordinate multiple programmers
- Useful for “hacking” single-use/personal-use programs: start with empty program and debug until it works

Software Processes

Waterfall Model

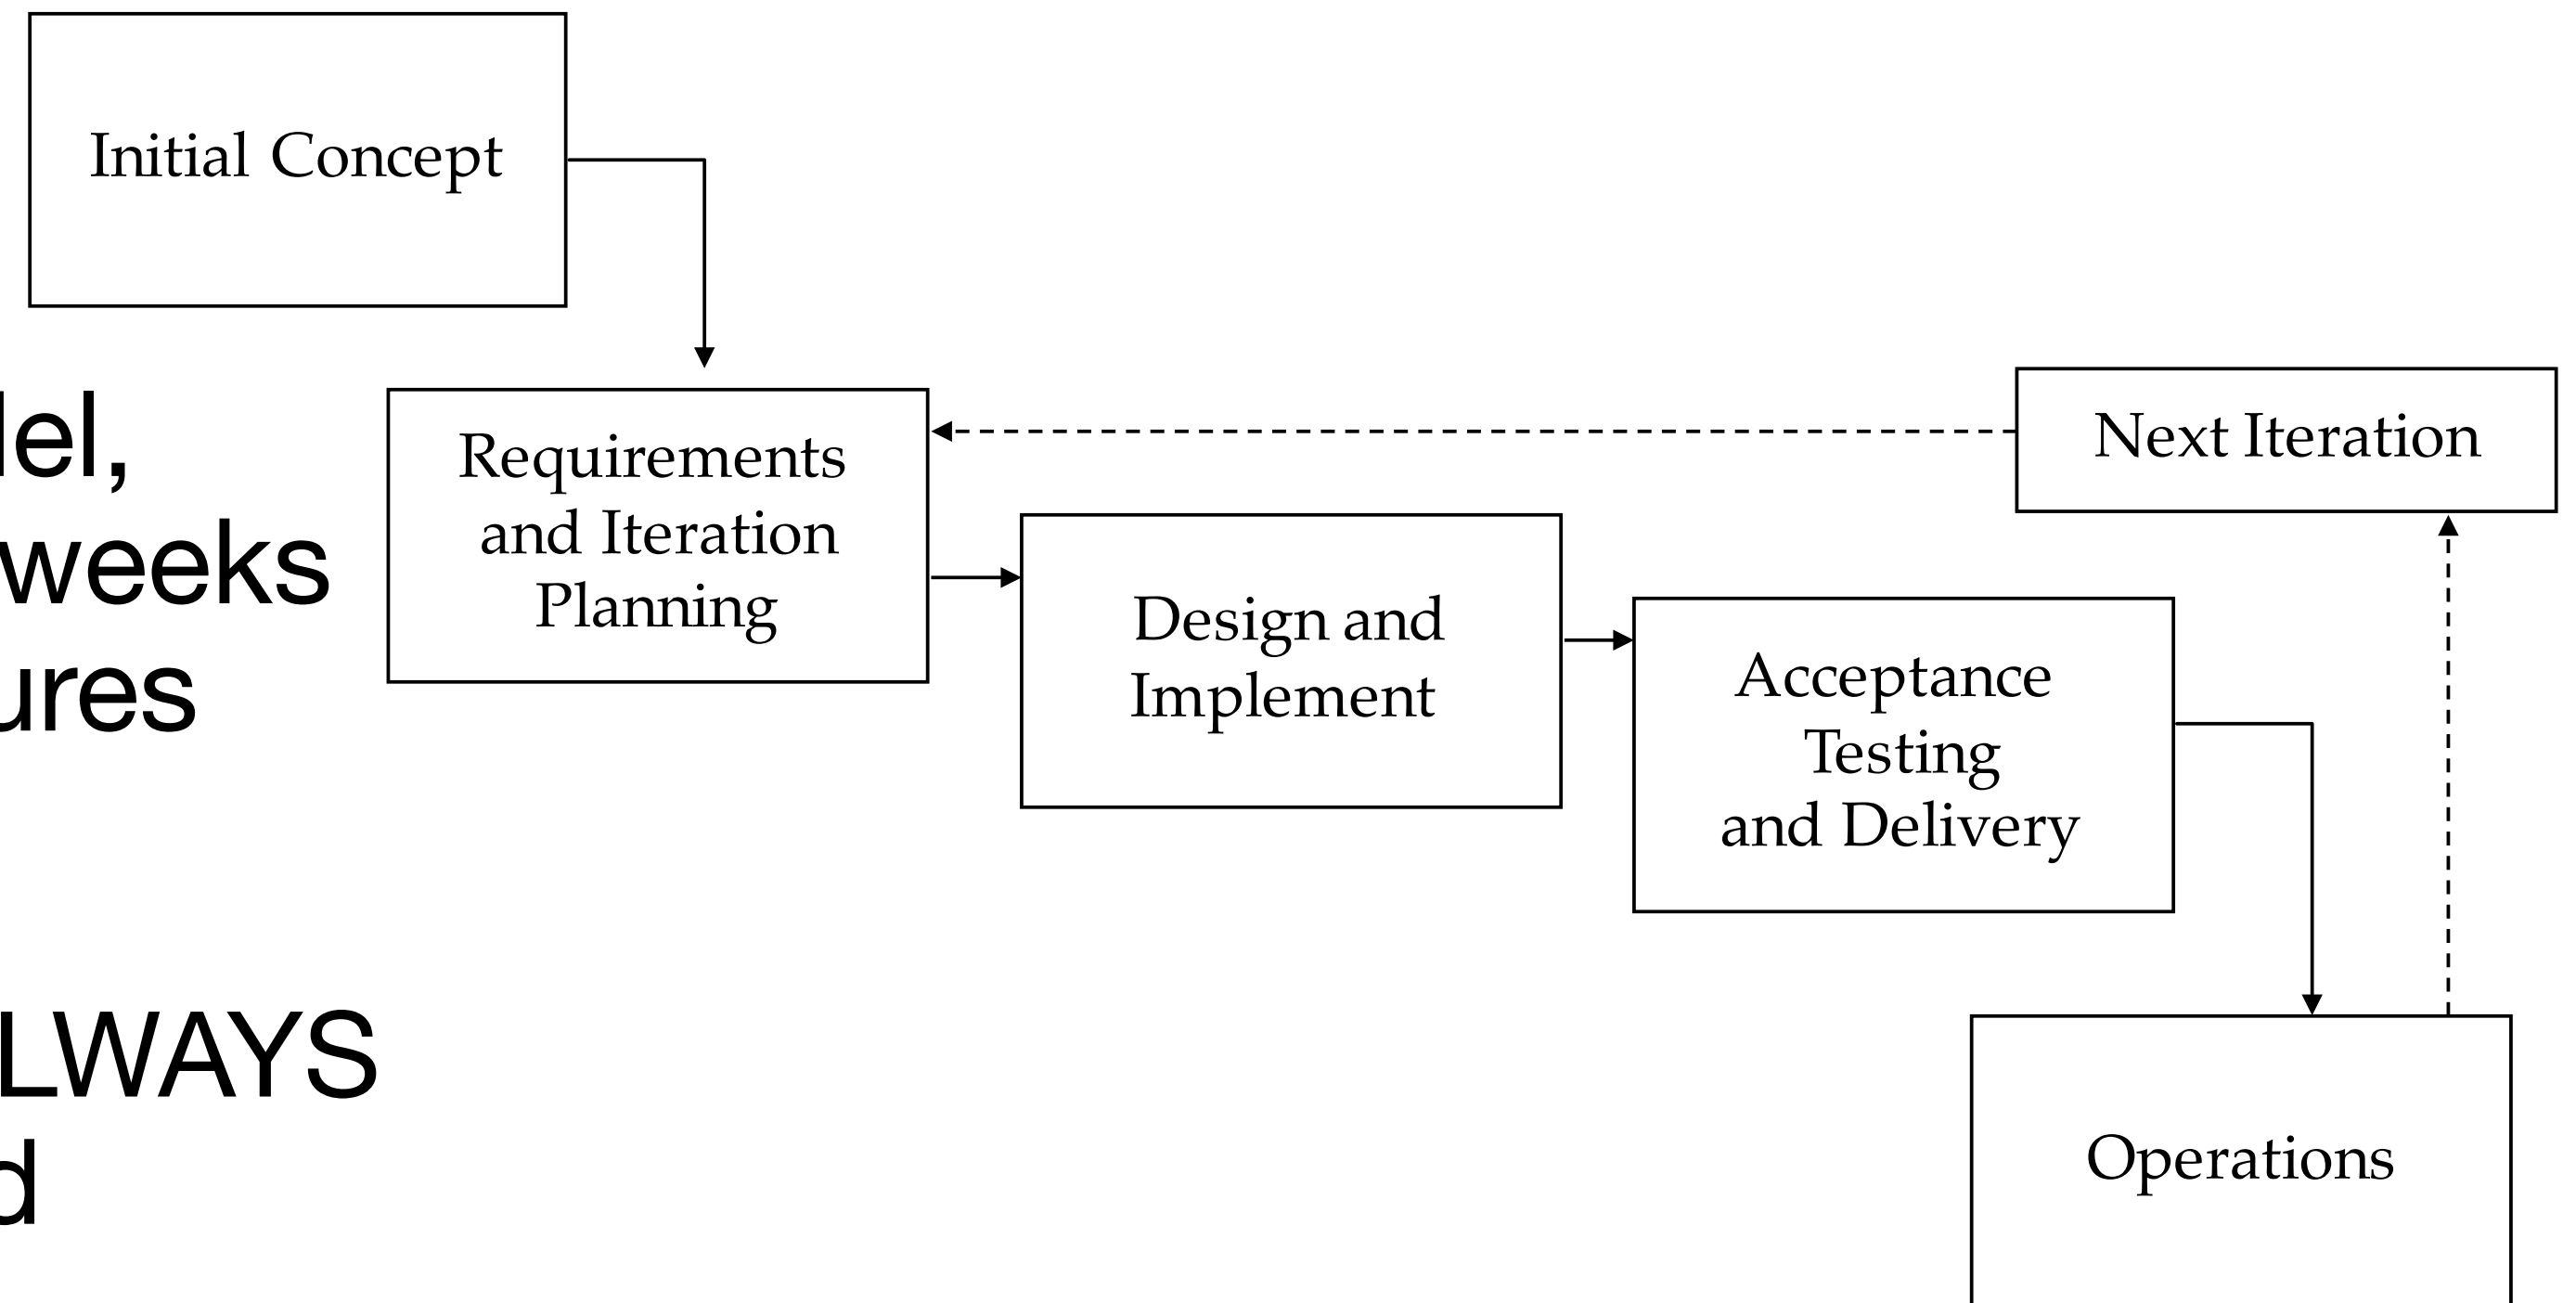

- Widely used today
- Advantages
 - Measurable progress
 - Experience applying steps in past projects can be used in estimating duration of “similar” steps in future projects
 - Produces software artifacts that can be re-used in other projects
- Disadvantages
 - Difficulty of accommodating change after the process is underway: One phase has to be complete before moving onto the next phase.

Software Processes

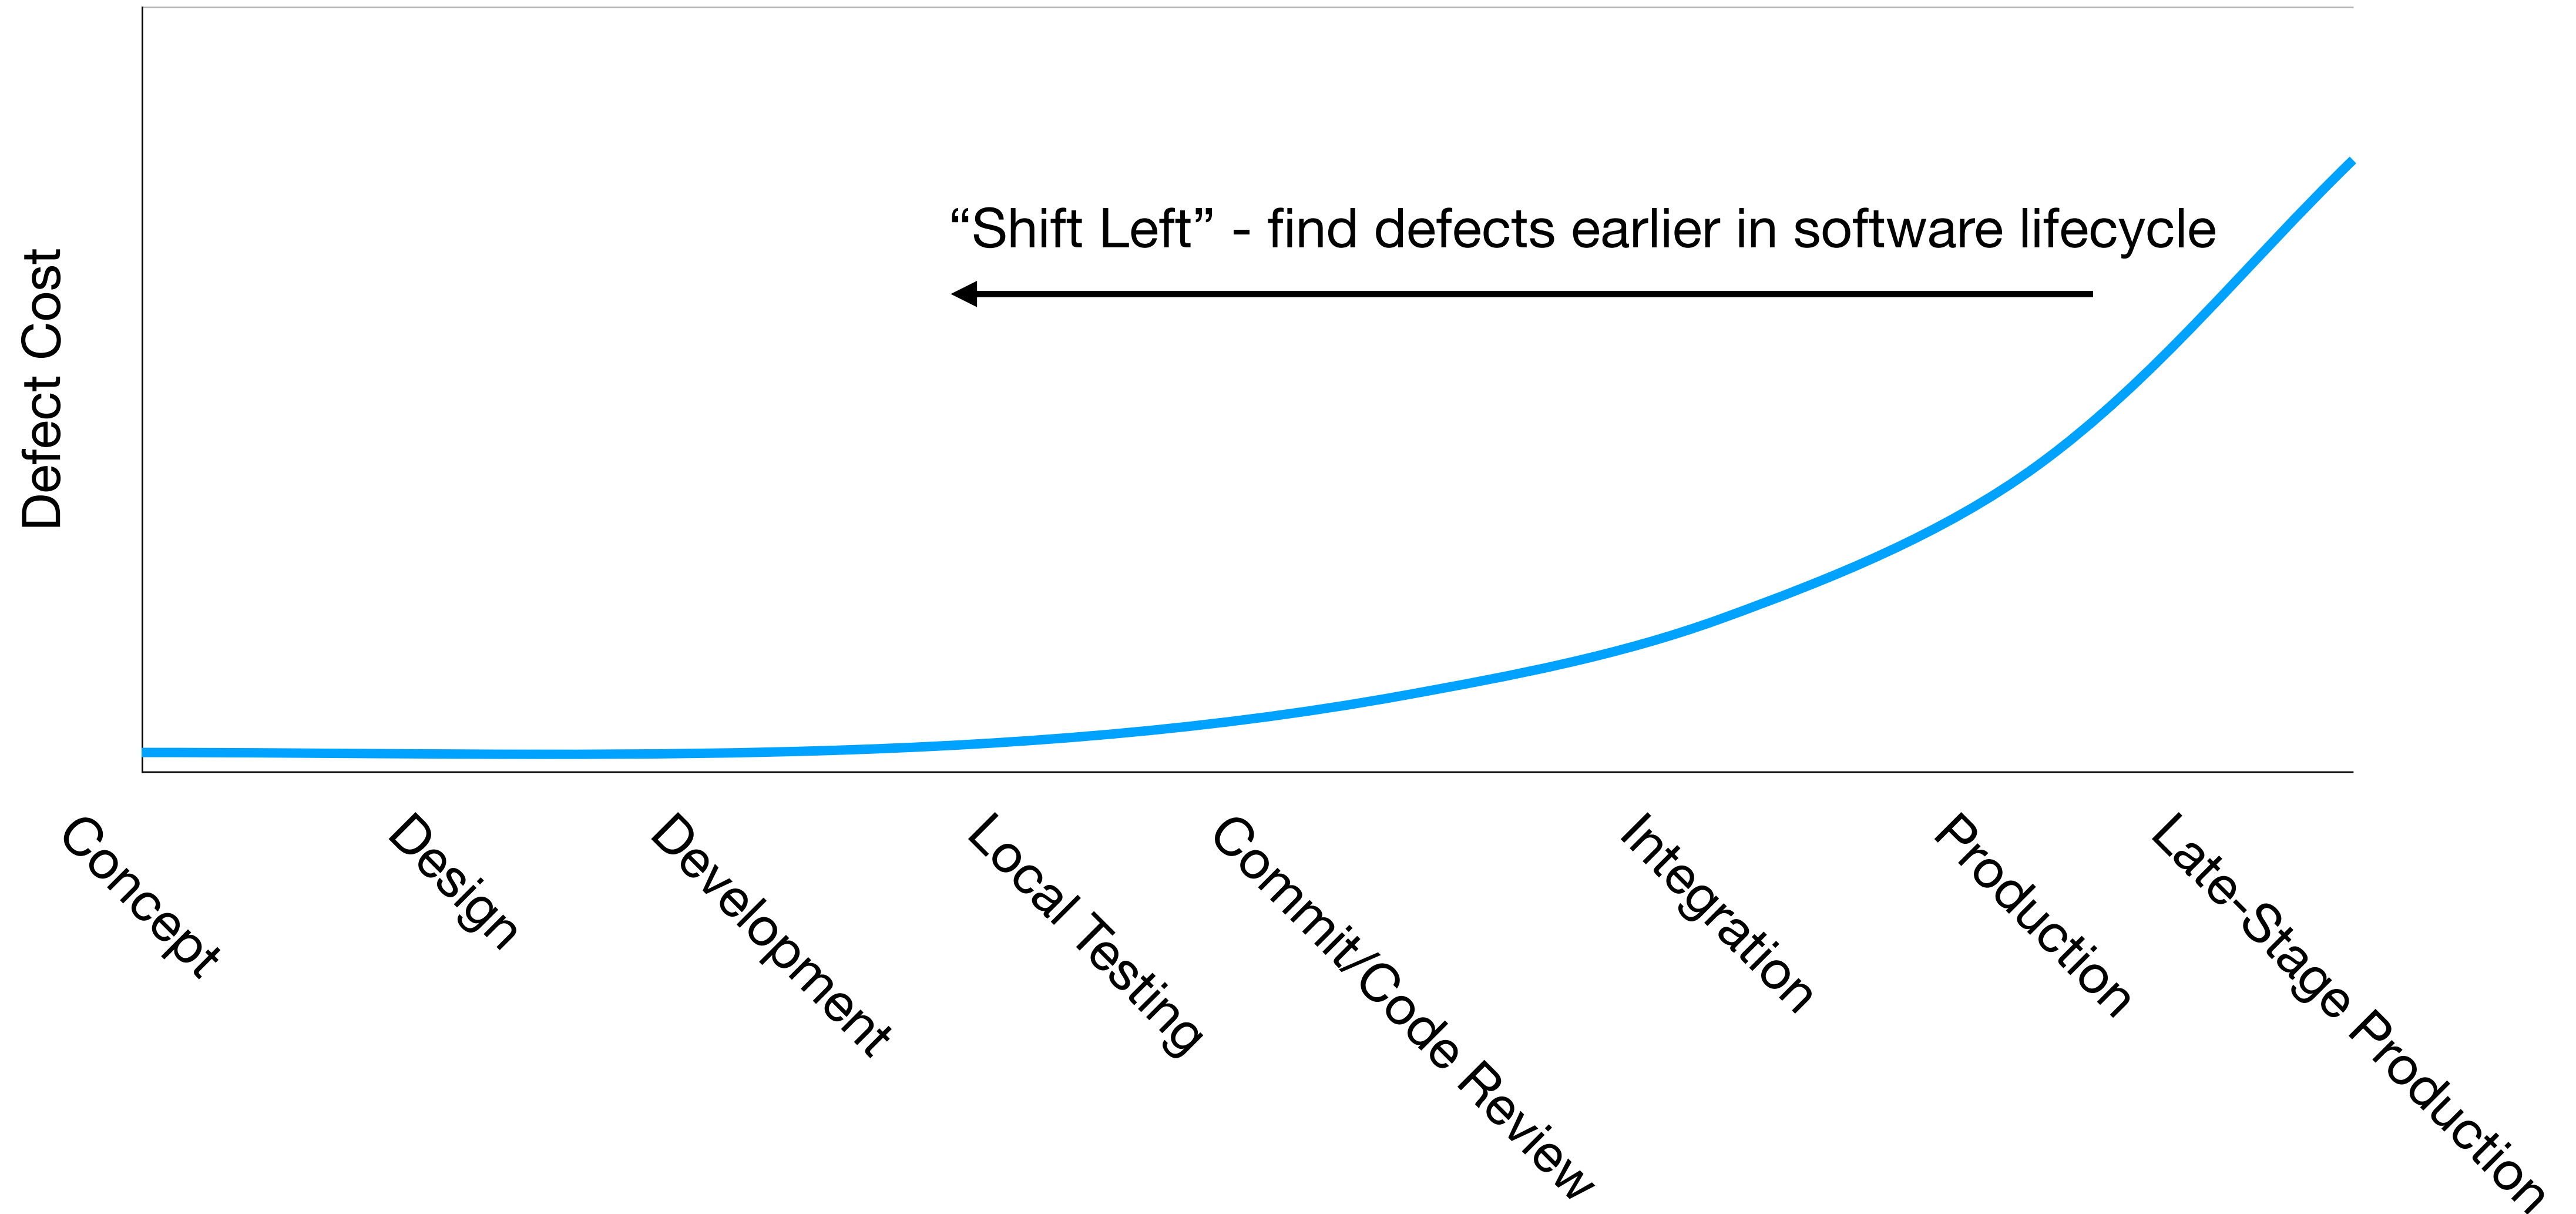

Agile Model

- Agile results in an *iterative* model, where each iteration is several weeks long and results in several features being built
- Recognize that requirements **ALWAYS** evolve as you are trying to build something
- Plus, maybe you can get useful feedback by delivering a partial app early

Cost to Fix a Defect Over Time

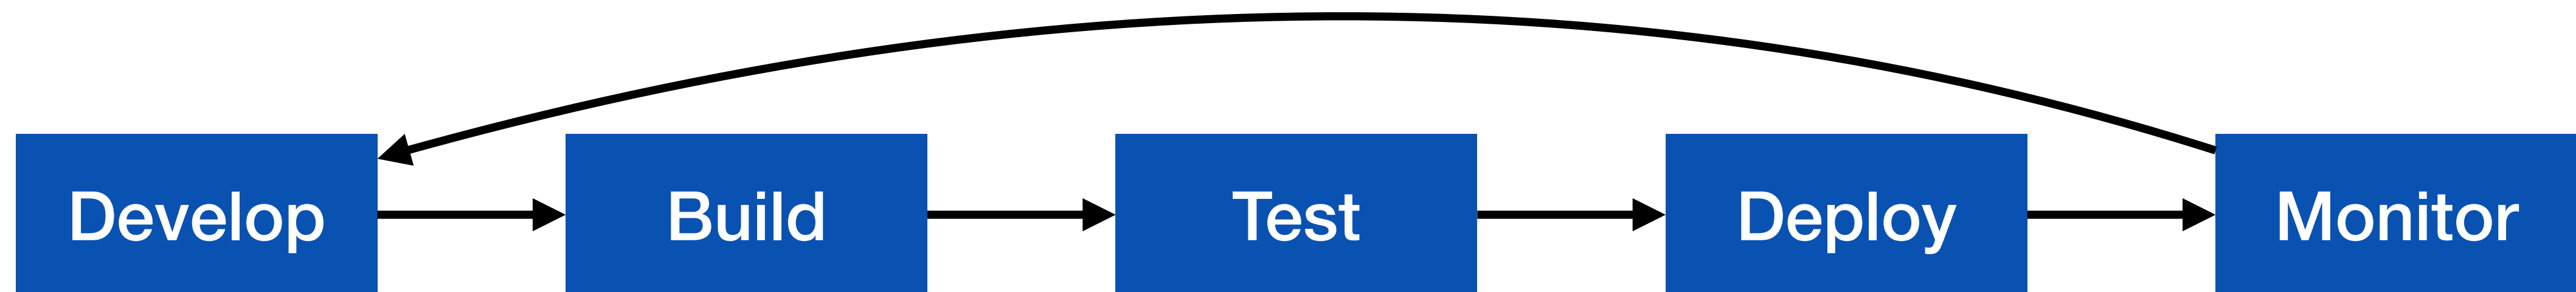

Rough Estimate

Software Processes

Continuous Development

- Like agile, but...
 - Fast feedback loops
 - We have a formal mechanism for deploying new versions of code and validating (test/staging/production)

Why Continuous Development?

Unblocking developers and increasing velocity

Why Continuous Development?

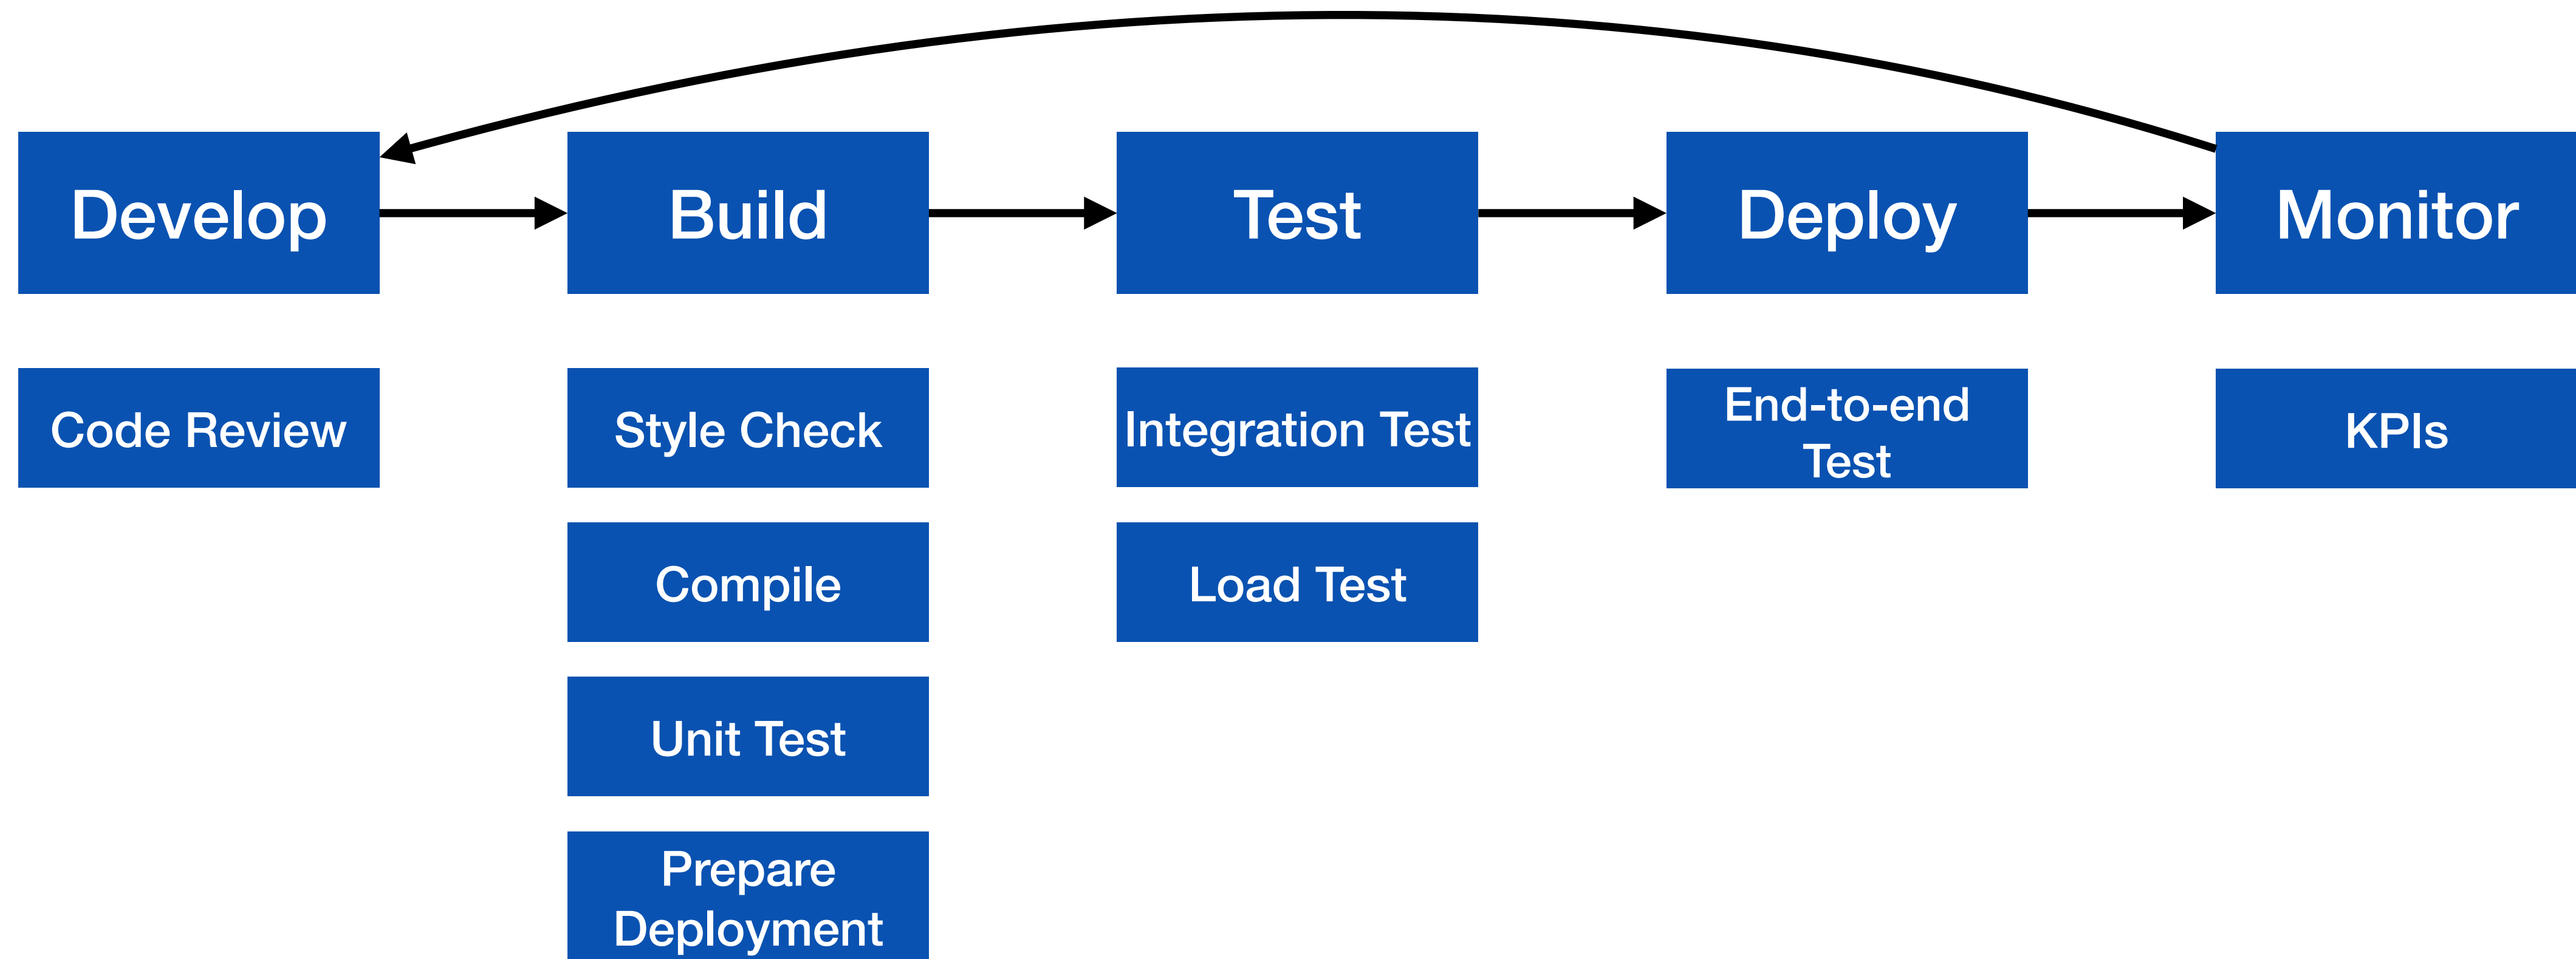

Improving the end-user experience

If you have:
 1
 5
 10
 100
 1,000
 developers working on your product

How often can you **deliver** your customers:
 Bug fixes
 Security patches
 Feature enhancements
 New features

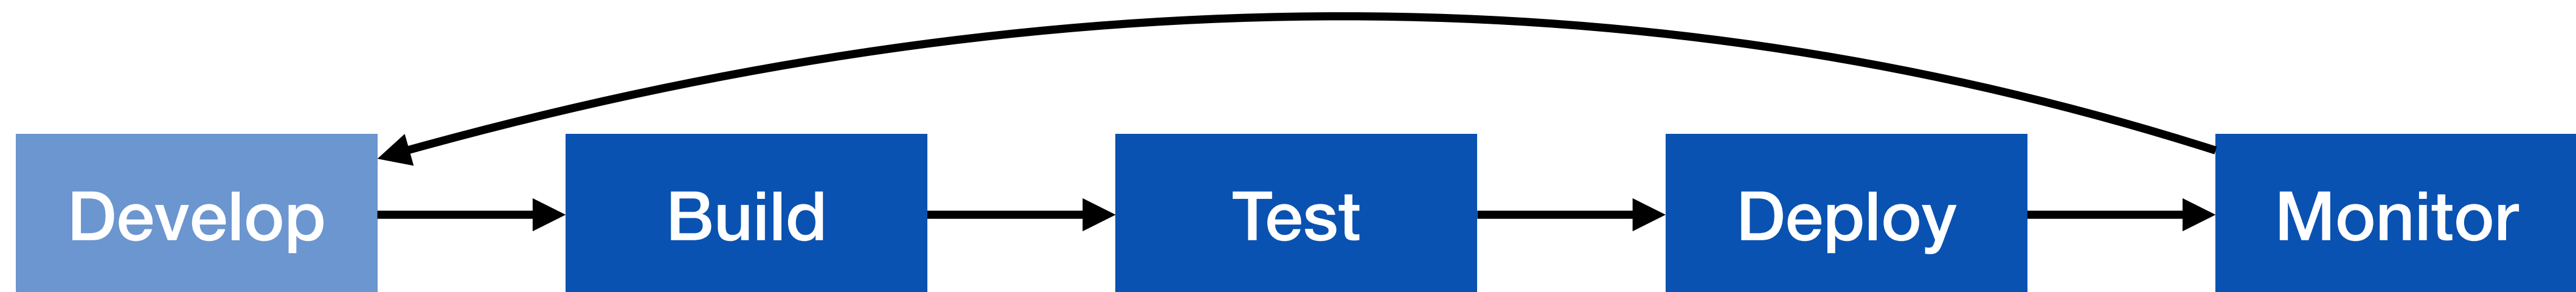

Continuous Development

Improving quality & velocity with frequent, fast feedback loops

Roadmap for this week

- Continuous development overview (this lesson)
- “Shifting left” with continuous integration
- Deployment infrastructure
- Continuous delivery
